

What is AWS SAM and how does it relate to CloudFormation?

Follow-up: When would you choose SAM over CDK or plain CloudFormation for serverless applications?

🟡 What is AWS SAM?

AWS SAM stands for **Serverless Application Model**.

It's a **tool** that helps you build and deploy **serverless applications** on AWS **easily and quickly**.

☁ Serverless means:

- You don't manage servers.
- You use AWS services like **Lambda**, **API Gateway**, and **DynamoDB**.
- AWS automatically handles the scaling and infrastructure.

🔑 What Does SAM Do?

🌿 Imagine CloudFormation is like writing code in assembly (low-level, long, complex).

👉 **SAM is like Python** — short, clean, and easy.

With just a **few lines of YAML**, you can:

- Define a **Lambda function**
- Attach an **API Gateway**
- Connect to **DynamoDB**
- Set **permissions** — all together!

🔄 How SAM Works

1. You write a simple YAML file (template.yaml)
2. You use the **SAM CLI** to:
 - Build the code (sam build)
 - Deploy to AWS (sam deploy)
 - Test locally (sam local start-api)
3. Behind the scenes, SAM converts your YAML into **CloudFormation**.
 - So you still get rollback, versioning, audit logs — all benefits of infrastructure-as-code.

When Should You Use SAM?

Use Case	Use SAM	Use CDK	Use CloudFormation
Simple Serverless App (Lambda + API)	✅ Best	✅ Possible	✅ Possible
You like YAML	✅ Yes	❌ No	✅ Yes
Need Local Testing	✅ Yes (SAM CLI)	⬢ Some support	❌ None
Complex Logic / Reuse	❌ No	✅ Best	⬢ Verbose
Large Infra Teams	⬢ OK	✅ Best	✅ Yes

Real-World Example: Hello World API

Project Structure

cpp

sam-app/

```
├── template.yaml
├── hello_world/
│   ├── app.py
│   └── requirements.txt
```

template.yaml

yaml

AWSTemplateFormatVersion: '2010-09-09'

Transform: AWS::Serverless-2016-10-31

Resources:

HelloWorldFunction:

Type: AWS::Serverless::Function

Properties:

CodeUri: hello_world/

Handler: app.lambda_handler

Runtime: python3.9

Events:

HelloApi:

Type: Api

Properties:

Path: /hello

Method: GET

app.py

python

```
def lambda_handler(event, context):
```

```
    return {
        "statusCode": 200,
        "body": "Hello from SAM!"
    }
```

Deploy & Test

bash

sam build

sam deploy --guided # You'll get a public URL

👁 You get:

<https://<your-api>.execute-api.us-east-1.amazonaws.com/Prod/hello>

🔧 **Test Locally:**

bash

sam local start-api

Visit: <http://localhost:3000/hello>

AWS SAM is great for **building small, serverless apps using Lambda and API Gateway**. It saves time **by reducing YAML**, allows **local testing with SAM CLI**, and still uses CloudFormation underneath. I used SAM to build a REST API for a startup in days, tested locally, and deployed with a single command — it was fast, reliable, and serverless from day one.

What is AWS SAM primarily used for?

- A. Automating EC2 deployments
- B. Building and deploying serverless applications on AWS
- C. Creating Kubernetes clusters
- D. Visualizing infrastructure

Answer: B

What does AWS SAM transform into before actual resource provisioning?

- A. Docker Compose
- B. Terraform scripts
- C. Native CloudFormation templates
- D. AWS Lambda runtime

Answer: C

4. Which AWS service does not directly benefit from AWS SAM's high-level abstractions?

- A. Lambda
- B. API Gateway
- C. DynamoDB
- D. EC2

Answer: D
